Cache Memories

Introduction to Computer Systems 13th Lecture, Oct. 24, 2022

Instructors:

Class 1: Chen Xiangqun, Liu Xianhua

Class 2: Guan Xuetao

Class 3: Lu Junlin

Today

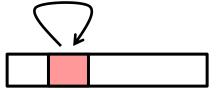

- Cache memory organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

Recall: Locality

 Principle of Locality: Programs tend to use data and instructions with addresses near or equal to those they have used recently

 Recently referenced items are likely to be referenced again in the near future

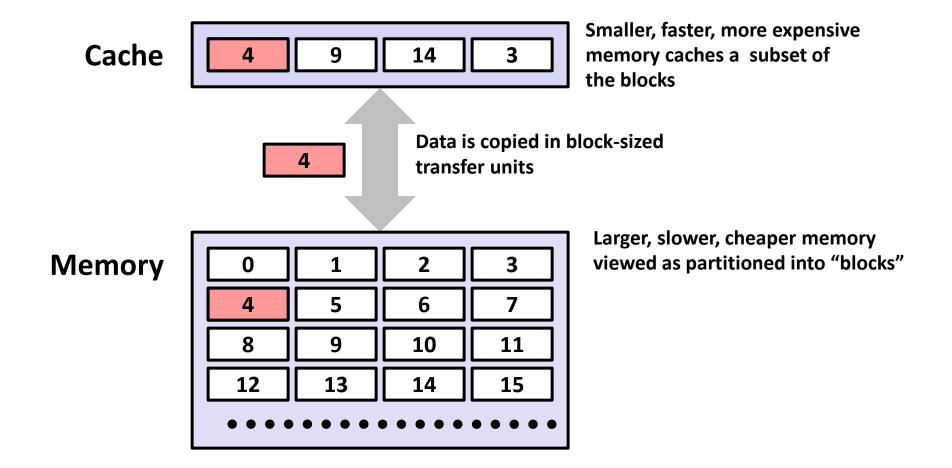

Spatial locality:

 Items with nearby addresses tend to be referenced close together in time

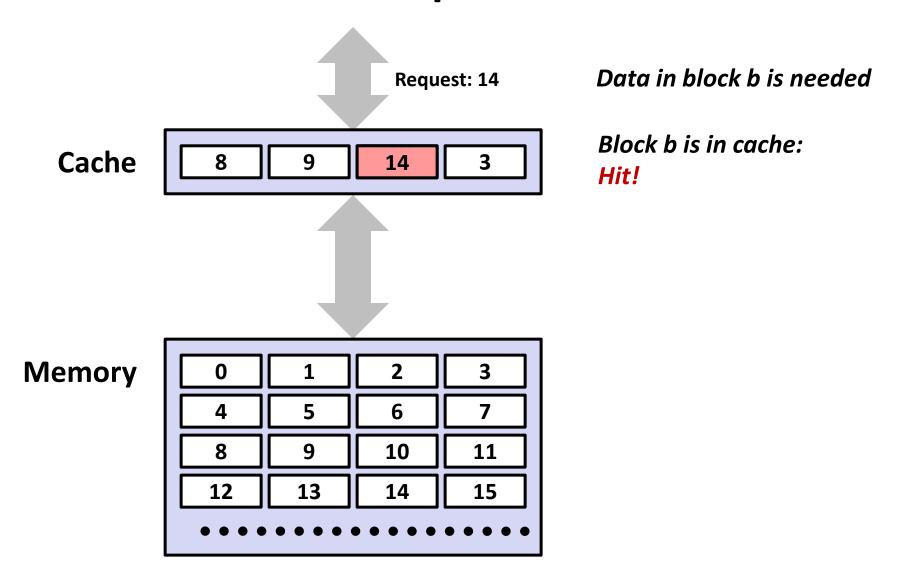

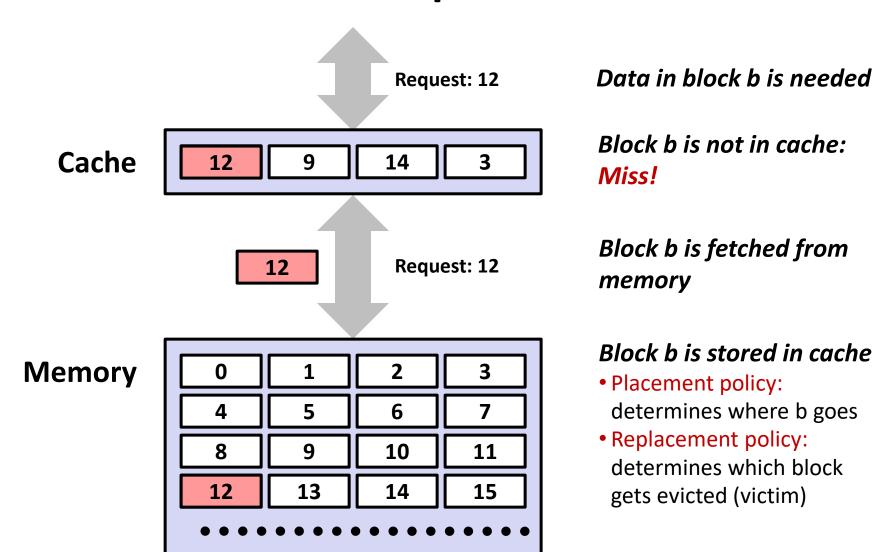

Recall: General Cache Concepts

General Cache Concepts: Hit

General Cache Concepts: Miss

Recall: General Caching Concepts: 3 Types of Cache Misses

■ Cold (compulsory) miss

 Cold misses occur because the cache starts empty and this is the first reference to the block.

Capacity miss

 Occurs when the set of active cache blocks (working set) is larger than the cache.

Conflict miss

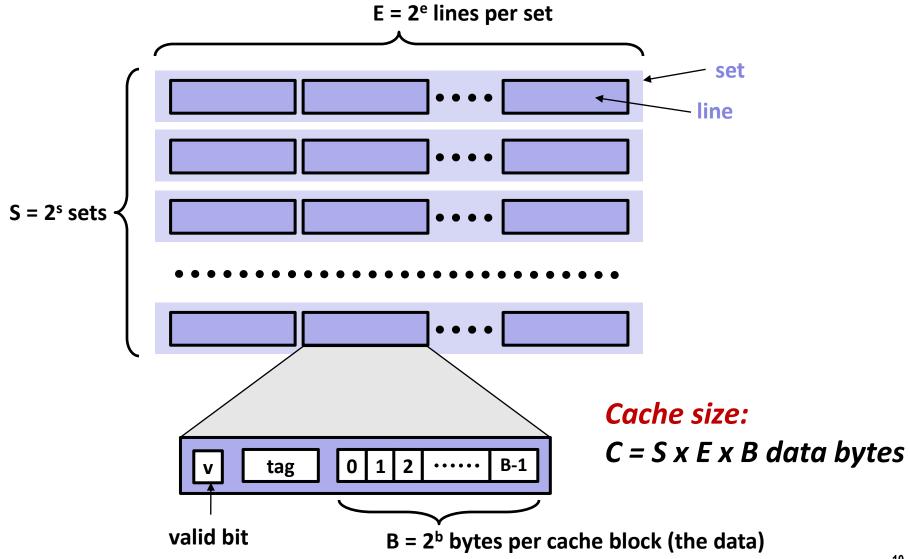

- Most caches limit blocks at level k+1 to a small subset (sometimes a singleton) of the block positions at level k.
 - E.g. Block i at level k+1 must be placed in block (i mod 4) at level k.
- Conflict misses occur when the level k cache is large enough, but multiple data objects all map to the same level k block.
 - E.g. Referencing blocks 0, 8, 0, 8, 0, 8, ... would miss every time.

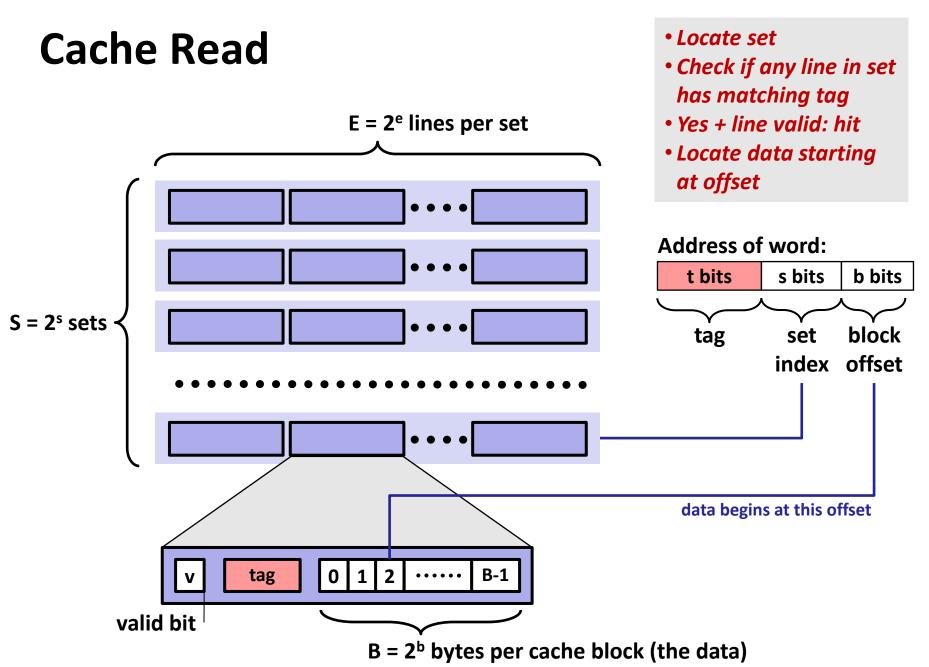

Cache Memories

- Cache memories are small, fast SRAM-based memories managed automatically in hardware
 - Hold frequently accessed blocks of main memory
- CPU looks first for data in cache
- Typical system structure:

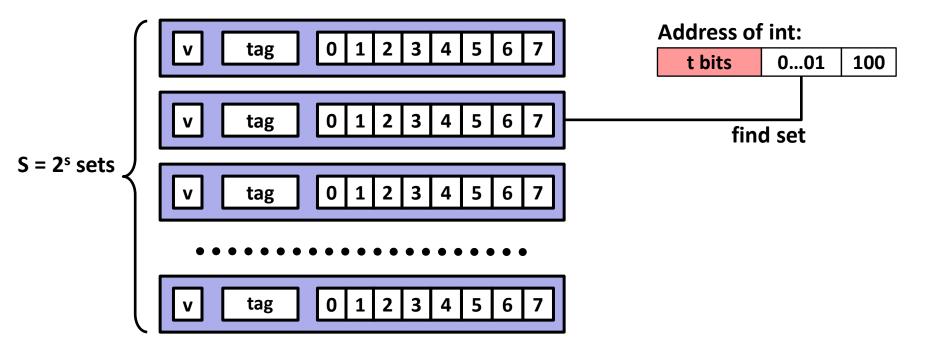

General Cache Organization (S, E, B)

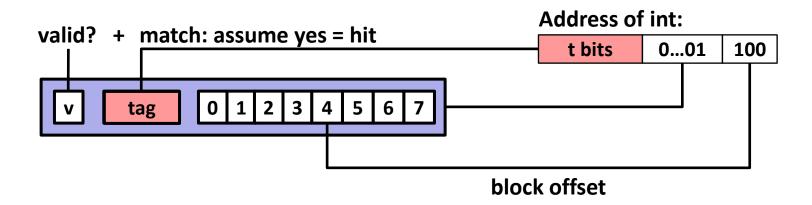

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size 8 bytes

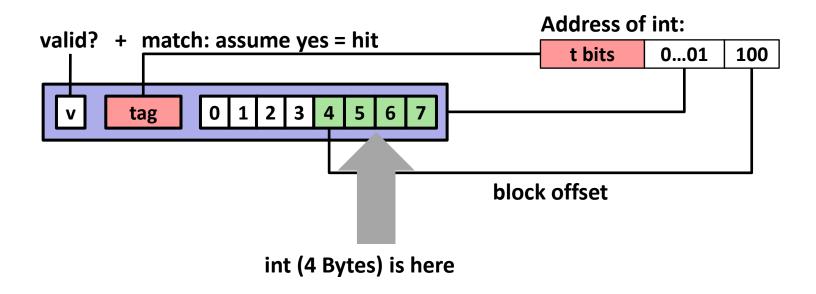

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size 8 bytes

Example: Direct Mapped Cache (E = 1)

Direct mapped: One line per set Assume: cache block size 8 bytes

If tag doesn't match: old line is evicted and replaced

Direct-Mapped Cache Simulation

t=1	s=2	b=1
X	XX	Х

4-bit addresses (address space size M=16 bytes) S=4 sets, E=1 Blocks/set, B=2 bytes/block

Address trace (reads, one byte per read):

0	$[0000_2],$	miss
1	$[0001_{2}],$	hit
7	$[0111_2],$	miss
8	$[1000_{2}],$	miss
0	[0000]	miss

	V	Tag	Block
Set 0	1	0	M[0-1]
Set 1	0		
Set 2	0		
Set 3	1	0	M[6-7]

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set Assume: cache block size 8 bytes Address of short int: 0...01 t bits 100 0 1 2 3 4 5 6 tag find set 0 | 1 | 2 | 3 | 4 | 5 | 6 7 0 | 1 | 2 | 3 | tag tag 0 1 2 3 4 5 6 7 tag 3 4 0 5 6

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set

E-way Set Associative Cache (Here: E = 2)

E = 2: Two lines per set Assume: cache block size 8 bytes Address of short int: t bits 0...01 100 compare both valid? + match: yes = hit 0 | 1 | 2 | 3 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 6 | 7 tag tag block offset

No match:

One line in set is selected for eviction and replacement

short int (2 Bytes) is here

Replacement policies: random, least recently used (LRU), ...

2-Way Set Associative Cache Simulation

t=2	s=1	b=1
ХХ	X	Х

4-bit addresses (M=16 bytes) S=2 sets, E=2 blocks/set, B=2 bytes/block

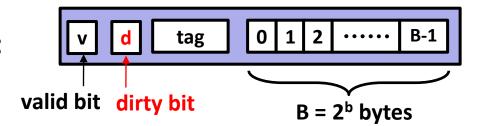

Address trace (reads, one byte per read):

0	$[00\underline{0}0_2],$	miss
1	$[0001_2],$	hit
7	$[01\underline{1}1_2],$	miss
8	$[10\underline{0}0_2],$	miss
0	[00002]	hit

	V	Tag	Block
Set 0	1	00	M[0-1]
	1	10	M[8-9]
	4	01	NAIC 71
Set 1	1	01	M[6-7]
	0		

What about writes?

- Multiple copies of data exist:
 - L1, L2, L3, Main Memory, Disk

What to do on a write-hit?

- Write-through (write immediately to memory)
- Write-back (defer write to memory until replacement of line)
 - Each cache line needs a dirty bit (set if data has been written to)

What to do on a write-miss?

- Write-allocate (load into cache, update line in cache)
 - Good if more writes to the location will follow
- No-write-allocate (writes straight to memory, does not load into cache)

Typical

- Write-through + No-write-allocate
- Write-back + Write-allocate

Practical Write-back Write-allocate

- A write to address X is issued
- valid bit dirty bit $B = 2^b$ bytes

- If it is a hit
 - Update the contents of block
 - Set dirty bit to 1 (bit is sticky and only cleared on eviction)

If it is a miss

- Fetch block from memory (per a read miss)
- The perform the write operations (per a write hit)

If a line is evicted and dirty bit is set to 1

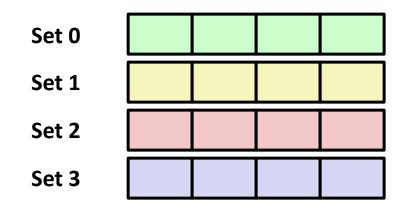

- The entire block of 2^b bytes are written back to memory
- Dirty bit is cleared (set to 0)
- Line is replaced by new contents

Why Index Using Middle Bits?

Direct mapped: One line per set Assume: cache block size 8 bytes **Standard Method:** Middle bit indexing Address of int: 3 tag 0...01 100 t bits 3 5 tag find set $S = 2^s$ sets 3 5 tag **Alternative Method: High bit indexing** Address of int: 1...11 t bits 3 100 tag 5 6 find set

Illustration of Indexing Approaches

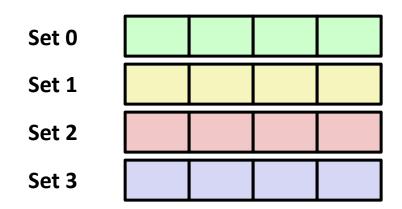

- 64-byte memory
 - 6-bit addresses
- 16 byte, direct-mapped cache
- Block size = 4. (Thus, 4 sets; why?)
- 2 bits tag, 2 bits index, 2 bits offset

		0000xx
		0001xx
		0010xx
		0011xx
		0100xx
		0101xx
		0110xx
		0111xx
		1000xx
		1001xx
		1010xx
		1011xx
		1100xx
		1101xx
		1110xx
		1111xx
) 25

Middle Bit Indexing

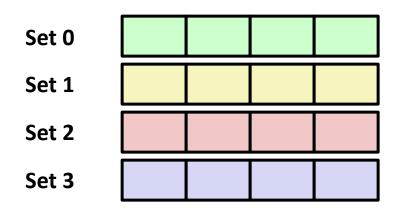

- Addresses of form TTSSBB
 - **TT** Tag bits
 - Set index bits
 - BB Offset bits
- Makes good use of spatial locality

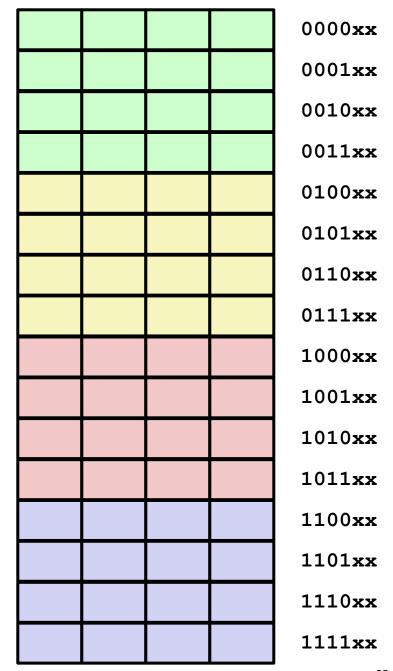

High Bit Indexing

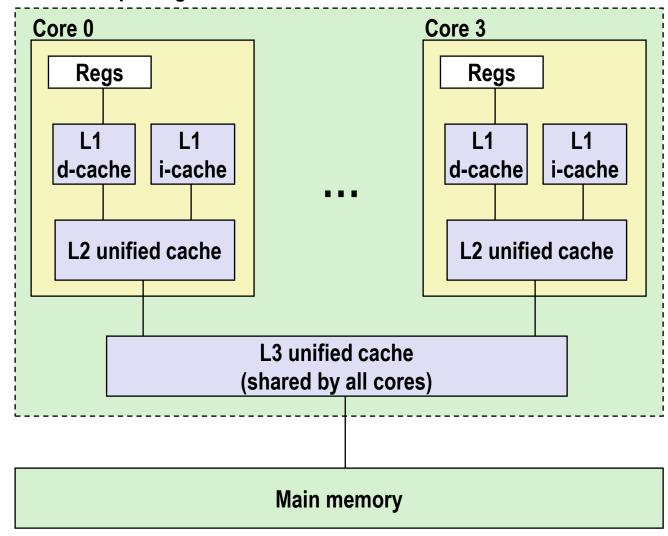

- Addresses of form SSTTBB
 - Set index bits
 - **TT** Tag bits
 - **BB** Offset bits
- Program with high spatial locality would generate lots of conflicts

Intel Core i7 Cache Hierarchy

Processor package

L1 i-cache and d-cache:

32 kB, 8-way, Access: 4 cycles

L2 unified cache:

256 kB, 8-way, Access: 10 cycles

L3 unified cache:

8 MB, 16-way,

Access: 40-75 cycles

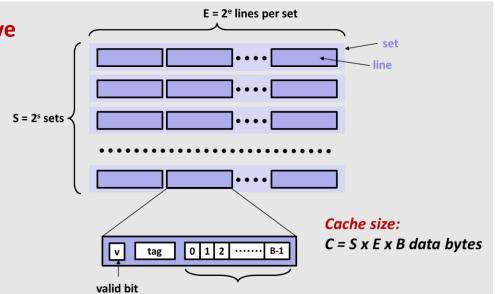

Block size: 64 bytes for

all caches.

Example: Core i7 L1 Data Cache

32 kB 8-way set associative 64 bytes/block

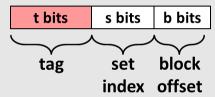

47 bit address range

		YIS ON!
He	t per	imany Binary

Set index: 0x??

Tag: 0x??

Example: Core i7 L1 Data Cache

32 kB 8-way set associative

64 bytes/block

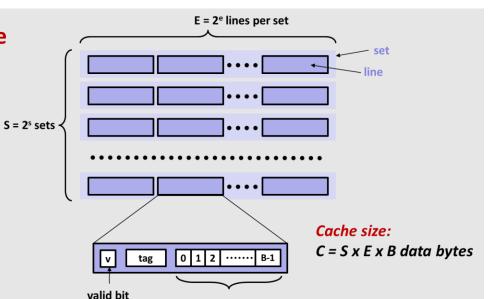

47 bit address range

$$B = 64$$

$$S = 64, s = 6$$

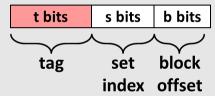

$$E = 8, e = 3$$

$$C = 64 \times 64 \times 8 = 32,768$$

Hex Decimal В

Block offset: 6 bits

Set index: 6 bits

Tag: 35 bits

Block offset: 0x10

Set index: 0x0

Tag: 0x7f7262a1e

Cache Performance Metrics

Miss Rate

- Fraction of memory references not found in cache (misses / accesses)
 = 1 hit rate
- Typical numbers (in percentages):
 - 3-10% for L1
 - can be quite small (e.g., < 1%) for L2, depending on size, etc.

Hit Time

- Time to deliver a line in the cache to the processor
 - includes time to determine whether the line is in the cache
- Typical numbers:
 - 4 clock cycle for L1
 - 10 clock cycles for L2

Miss Penalty

- Additional time required because of a miss
 - typically 50-200 cycles for main memory (Trend: increasing!)

Let's think about those numbers

- Huge difference between a hit and a miss
 - Could be 100x, if just L1 and main memory
- Would you believe 99% hits is twice as good as 97%?
 - Consider:
 cache hit time of 1 cycle
 miss penalty of 100 cycles
 - Average access time:

```
97% hits: 1 cycle + 0.03 * 100 cycles = 4 cycles
```

99% hits: 1 cycle + 0.01 * 100 cycles = 2 cycles

This is why "miss rate" is used instead of "hit rate"

Writing Cache Friendly Code

- Make the common case go fast
 - Focus on the inner loops of the core functions
- Minimize the misses in the inner loops
 - Repeated references to variables are good (temporal locality)
 - Stride-1 reference patterns are good (spatial locality)

Key idea: Our qualitative notion of locality is quantified through our understanding of cache memories

Today

- Cache organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

The Memory Mountain

- Read throughput (read bandwidth)
 - Number of bytes read from memory per second (MB/s)
- Memory mountain: Measured read throughput as a function of spatial and temporal locality.
 - Compact way to characterize memory system performance.

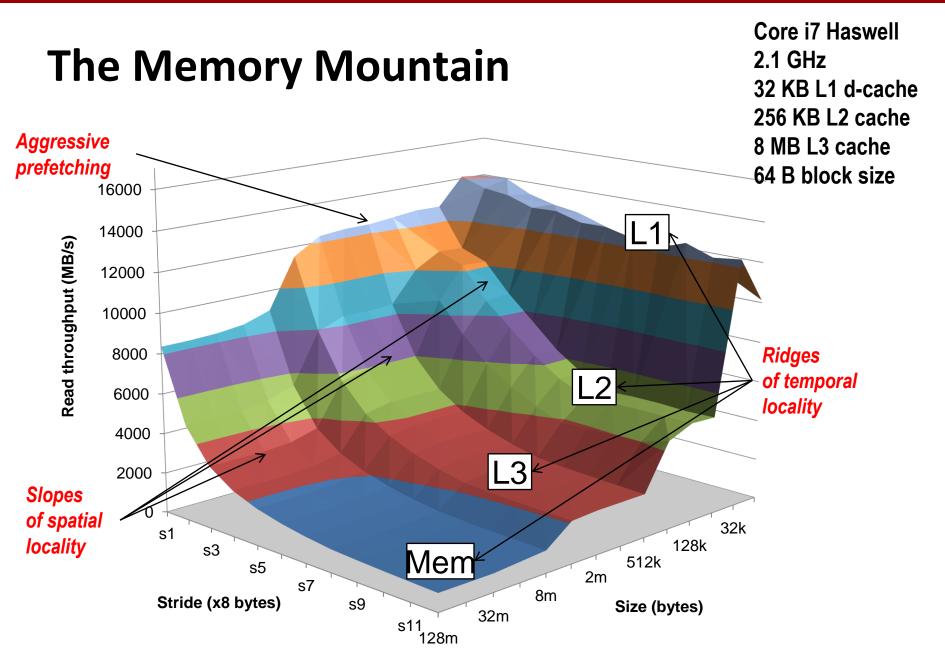

Memory Mountain Test Function

```
long data[MAXELEMS]; /* Global array to traverse */
/* test - Iterate over first "elems" elements of
      array "data" with stride of "stride", using
      using 4x4 loop unrolling.
*/
int test(int elems, int stride) {
  long i, sx2=stride*2, sx3=stride*3, sx4=stride*4;
  long acc0 = 0, acc1 = 0, acc2 = 0, acc3 = 0;
  long length = elems, limit = length - sx4;
  /* Combine 4 elements at a time */
  for (i = 0; i < limit; i += sx4)
    acc0 = acc0 + data[i];
    acc1 = acc1 + data[i+stride];
    acc2 = acc2 + data[i+sx2];
    acc3 = acc3 + data[i+sx3];
  /* Finish any remaining elements */
  for (; i < length; i++) {
    acc0 = acc0 + data[i];
  return ((acc0 + acc1) + (acc2 + acc3));
                                              mountain/mountain.c
```

Call test() with many combinations of elems and stride.

For each elems and stride:

- 1. Call test() once to warm up the caches.
- 2. Call test()
 again and measure
 the read
 throughput(MB/s)

Today

- Cache organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

Matrix Multiplication Example

Description:

- Multiply N x N matrices
- Matrix elements are doubles (8 bytes)
- O(N³) total operations
- N reads per source element
- N values summed per destination
 - but may be able to hold in register

```
/* ijk */
for (i=0; i<n; i++)

for (j=0; j<n; j++) {

   sum = 0.0; ←

   for (k=0; k<n; k++)

      sum += a[i][k] * b[k][j];

   c[i][j] = sum;

}

matmult/mm.c
```

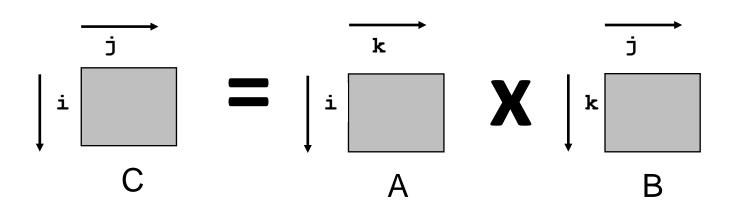

Miss Rate Analysis for Matrix Multiply

Assume:

- Block size = 32B (big enough for four doubles)
- Matrix dimension (N) is very large
 - Approximate 1/N as 0.0
- Cache is not even big enough to hold multiple rows

Analysis Method:

Look at access pattern of inner loop

Layout of C Arrays in Memory (review)

- C arrays allocated in row-major order
 - each row in contiguous memory locations
- Stepping through columns in one row:

```
for (i = 0; i < N; i++)
sum += a[0][i];</pre>
```

- accesses successive elements
- if block size (B) > sizeof(a_{ii}) bytes, exploit spatial locality
 - miss rate = sizeof(a_{ii}) / B

Stepping through rows in one column:

```
for (i = 0; i < n; i++)
sum += a[i][0];</pre>
```

- accesses distant elements
- no spatial locality!
 - miss rate = 1 (i.e. 100%)

Matrix Multiplication (ijk)

```
/* ijk */
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
    for (k=0; k<n; k++)
       sum += a[i][k] * b[k][j];
    c[i][j] = sum;
  }
}

matmult/mm.c</pre>
```

```

  for (j=0; j<n; j++) {
    r = b[k][j];
    for (i=0; i<n; i++)
        c[i][j] += a[i][k] * r;
  }
}
    matmult/mm.c</pre>
```

Misses per inner loop iteration:

<u>A</u>	<u>B</u>	<u>C</u>
1.0	0.0	1.0

Summary of Matrix Multiplication

```
for (i=0; i<n; i++) {
  for (j=0; j<n; j++) {
    sum = 0.0;
  for (k=0; k<n; k++)
    sum += a[i][k] * b[k][j];
  c[i][j] = sum;
}
</pre>
```

```
for (k=0; k<n; k++) {
  for (i=0; i<n; i++) {
    r = a[i][k];
  for (j=0; j<n; j++)
    c[i][j] += r * b[k][j];
}</pre>
```

```
for (j=0; j<n; j++) {
  for (k=0; k<n; k++) {
    r = b[k][j];
  for (i=0; i<n; i++)
    c[i][j] += a[i][k] * r;
}</pre>
```

ijk (& jik):

- 2 loads, 0 stores
- misses/iter = **1.25**

kij (& ikj):

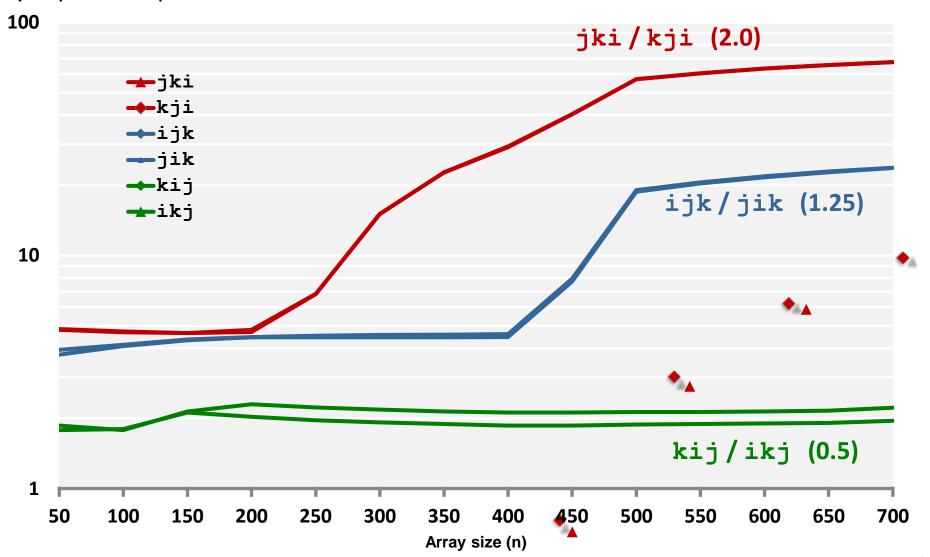

- 2 loads, 1 store
- misses/iter = **0.5**

jki (& kji):

- 2 loads, 1 store
- misses/iter = **2.0**

Core i7 Matrix Multiply Performance

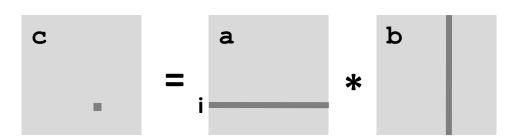

Cycles per inner loop iteration

Today

- Cache organization and operation
- Performance impact of caches
 - The memory mountain
 - Rearranging loops to improve spatial locality
 - Using blocking to improve temporal locality

Example: Matrix Multiplication

n

Cache Miss Analysis

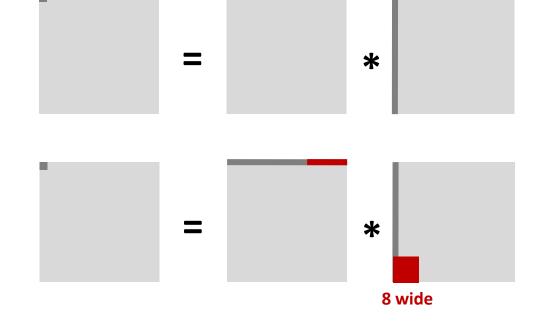

Assume:

- Matrix elements are doubles
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)

First iteration:

• n/8 + n = 9n/8 misses

Afterwards in cache: (schematic)

n

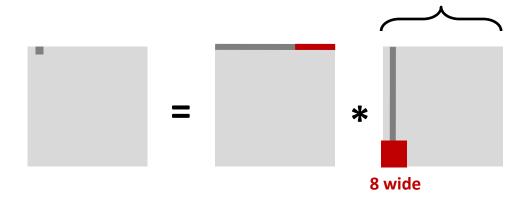

Cache Miss Analysis

Assume:

- Matrix elements are doubles.
- Cache block = 8 doubles
- Cache size C << n (much smaller than n)

Second iteration:

Again:n/8 + n = 9n/8 misses

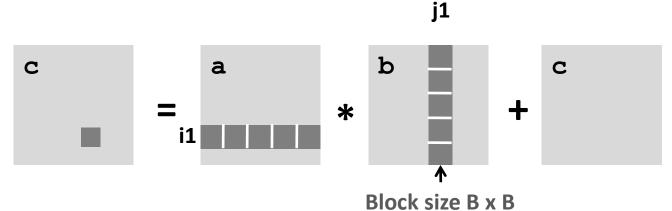

Total misses:

• $9n/8 * n^2 = (9/8) * n^3$

Blocked Matrix Multiplication

```
c = (double *) calloc(sizeof(double), n*n);
/* Multiply n x n matrices a and b */
void mmm(double *a, double *b, double *c, int n) {
    int i, j, k;
    for (i = 0; i < n; i+=B)
       for (i = 0; i < n; i+=B)
             for (k = 0; k < n; k+=B)
                /* B x B mini matrix multiplications */
                  for (i1 = i; i1 < i+B; i++)
                      for (j1 = j; j1 < j+B; j++)
                          for (k1 = k; k1 < k+B; k++)
                              c[i1*n+j1] += a[i1*n + k1]*b[k1*n + j1];
                                                         matmult/bmm.c
```

Cache Miss Analysis

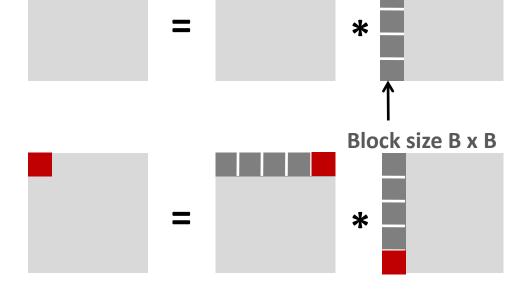

Assume:

- Cache block = 8 doubles
- Cache size C << n (much smaller than n)
- Three blocks fit into cache: 3B² < C</p>

First (block) iteration:

- B²/8 misses for each block
- 2n/B * B²/8 = nB/4 (omitting matrix c)

Afterwards in cache (schematic)

n/B blocks

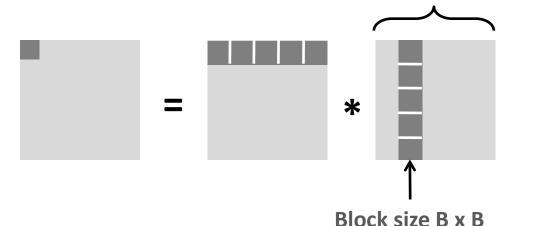

Cache Miss Analysis

Assume:

- Cache block = 8 doubles
- Cache size C << n (much smaller than n)
- Three blocks fit into cache: 3B² < C</p>

Second (block) iteration:

- Same as first iteration
- 2n/B * B²/8 = nB/4

Total misses:

• $nB/4 * (n/B)^2 = n^3/(4B)$

n/B blocks

Blocking Summary

- No blocking: (9/8) * n³
- Blocking: 1/(4B) * n³
- Suggest largest possible block size B, but limit 3B² < C!
- Reason for dramatic difference:
 - Matrix multiplication has inherent temporal locality:
 - Input data: 3n², computation 2n³
 - Every array elements used O(n) times!
 - But program has to be written properly

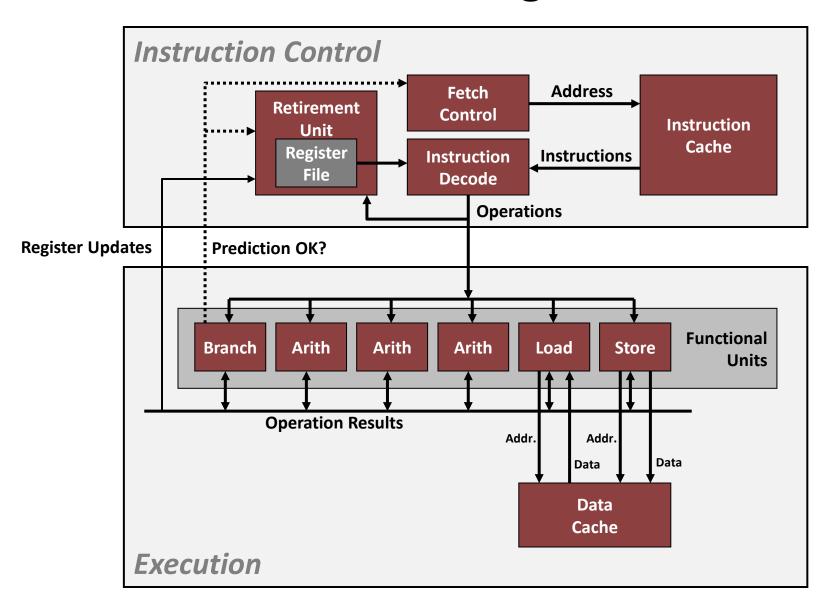

Cache Summary

Cache memories can have significant performance impact

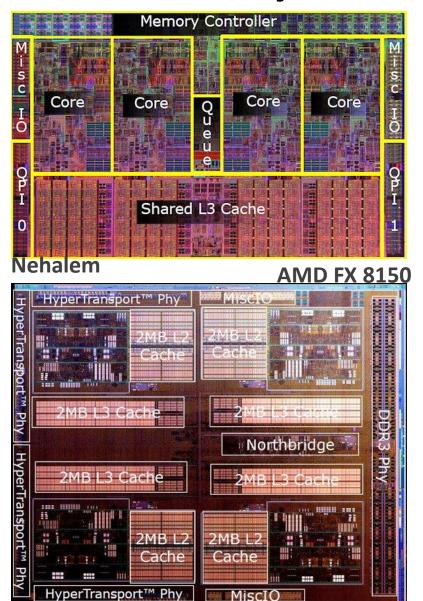

- You can write your programs to exploit this!
 - Focus on the inner loops, where bulk of computations and memory accesses occur.
 - Try to maximize spatial locality by reading data objects with sequentially with stride 1.
 - Try to maximize temporal locality by using a data object as often as possible once it's read from memory.
